The first step in RF circuit design is setting the DC bias level. Figure 1 shows one of the simplest bias circuits, the resistive divider used to bias the active device. The bias voltage, V_{bias} , is determined by the ratio of the two resistors. For the enhancement-mode MOSFET the bias voltage sets the voltage

vacuum tubes, whose function is processing time-varying signals, also require a steady current or voltage at their terminals to operate correctly. This current or voltage is a bias. The AC signal applied to them is superpositioned on this DC bias current or voltage. The operating point of a device, also known as bias point,

Bias Circuit A practical biasing configuration is shown in Figure 2. Bias current is delivered from a voltage supply V_{cc} through the resistor R_{bias} and the RF choke (inductor), shown as RFC in Figure 2. The resistor reduces the effect of device voltage (V_d) variation on the bias current by approximating a current source.
