In a nutshell, the turbine takes the heat and pressure generated by the engine and turns this energy into a spinning, circular motion. Much like a turbine at power generation plants (but much smaller), a turbocharger turbine uses rotational force to drive a compressor wheel (more on that later), which is essential for getting more air into the engine.

The diagram on the right clearly shows the air and oil flow through the turbocharger. As explained, the turbocharger is basically an air-compressor - it sucks in air and compresses it before pushing it out into the engine. An important part of the turbo-charger is therefore the compressor itself, identified by the number '1' in the picture. This is a specially designed rotary blade that when spun will suck air through

A turboshaft engine is a form of gas turbine that is optimized to produce shaftpower rather than jet thrust. In concept, turboshaft engines are very similar to turbojets, with additional turbine expansion to extract heat energy from the exhaust and convert it into output shaft power. They are even more similar to turboprops, with only minor differences, and a single engine is often sold in both ...
